How many genes are in this dataset?

```
nrow(counts)
```

```
## [1] 38694
```

Q2. How many 'control' cell lines do we have?

```
table(metadata$dex)
```

```
##
## control treated
##       4       4
```

```
#Extract IDs from control samples
inds <- metadata$dex == "control"
control.metadata <- metadata[inds,]
control.metadata$id
```

```
## [1] "SRR1039508" "SRR1039512" "SRR1039516" "SRR1039520"
```

```
#Check columns in two tables to be the same

metadata$id == colnames(counts)
```

```
## [1] TRUE TRUE TRUE TRUE TRUE TRUE TRUE TRUE
```

Toy differential gene expression

Note: this analysis is for demonstration only. NEVER do differential expression analysis this way!

```
# Note that the control samples are SRR1039508, SRR1039512, SRR1039516, and SRR1039520. This bit of cod

control <- metadata[metadata[,"dex"]=="control",]
control.counts <- counts[ ,control$id]
control.mean <- rowSums( control.counts )/4
head(control.mean)
```

```
## ENSG00000000003 ENSG00000000005 ENSG00000000419 ENSG00000000457 ENSG00000000460
##          900.75            0.00          520.50          339.75           97.25
## ENSG00000000938
##            0.75
```

Q3. How would you make the above code in either approach more robust?

Q4. Follow the same procedure for the treated samples (i.e. calculate the mean per gene across drug treated samples and assign to a labeled vector called treated.mean)

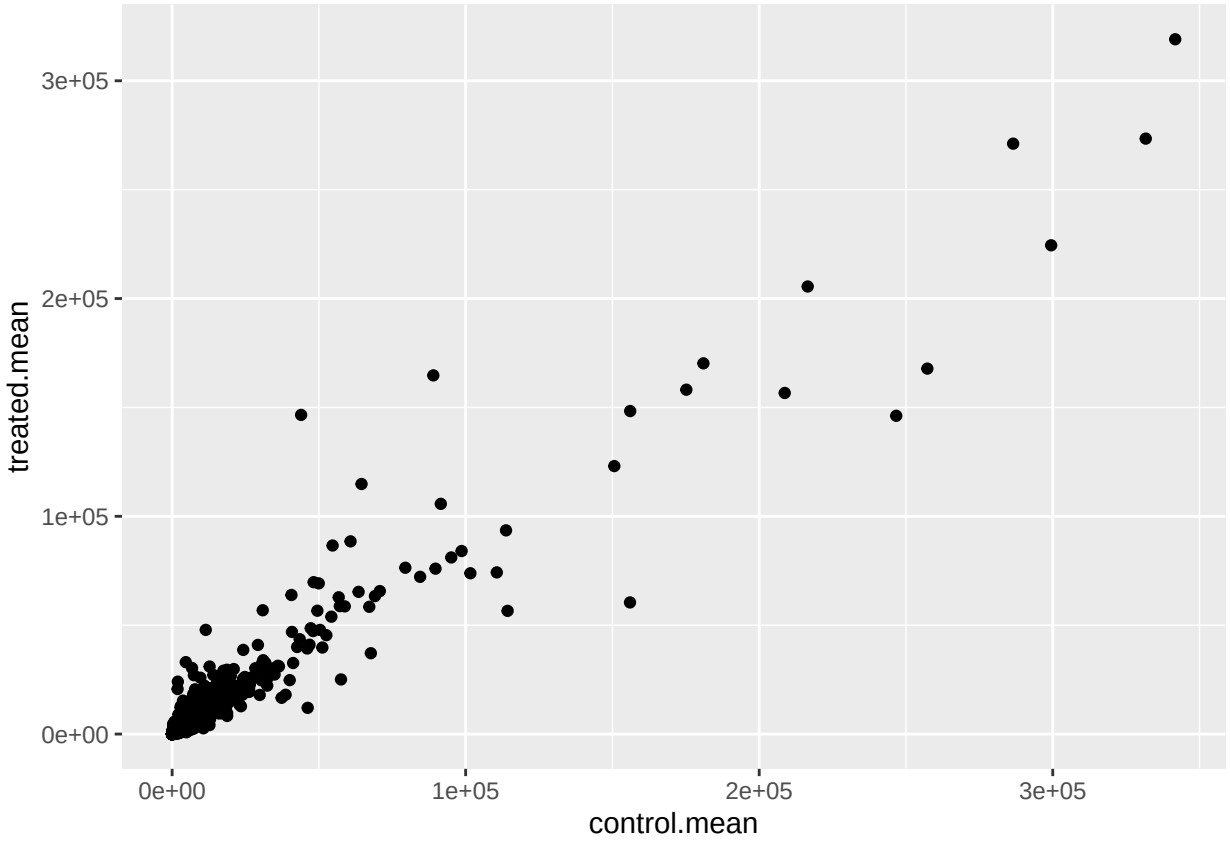
```
treated <- metadata[metadata[,"dex"]=="treated",]
treated.mean <- rowSums( counts[ ,treated$id] )/4
names(treated.mean) <- counts$ensgene
```

```
# combine our meancount data for bookkeeping purposes
meancounts <- data.frame(control.mean, treated.mean)
colSums(meancounts)
```

```
## control.mean treated.mean
##     23005324     22196524
```

Q5 (a). Create a scatter plot showing the mean of the treated samples against the mean of the control samples. Your plot should look something like the following.

```
library(ggplot2)
ggplot(meancounts, aes(control.mean, treated.mean)) +
  geom_point()
```

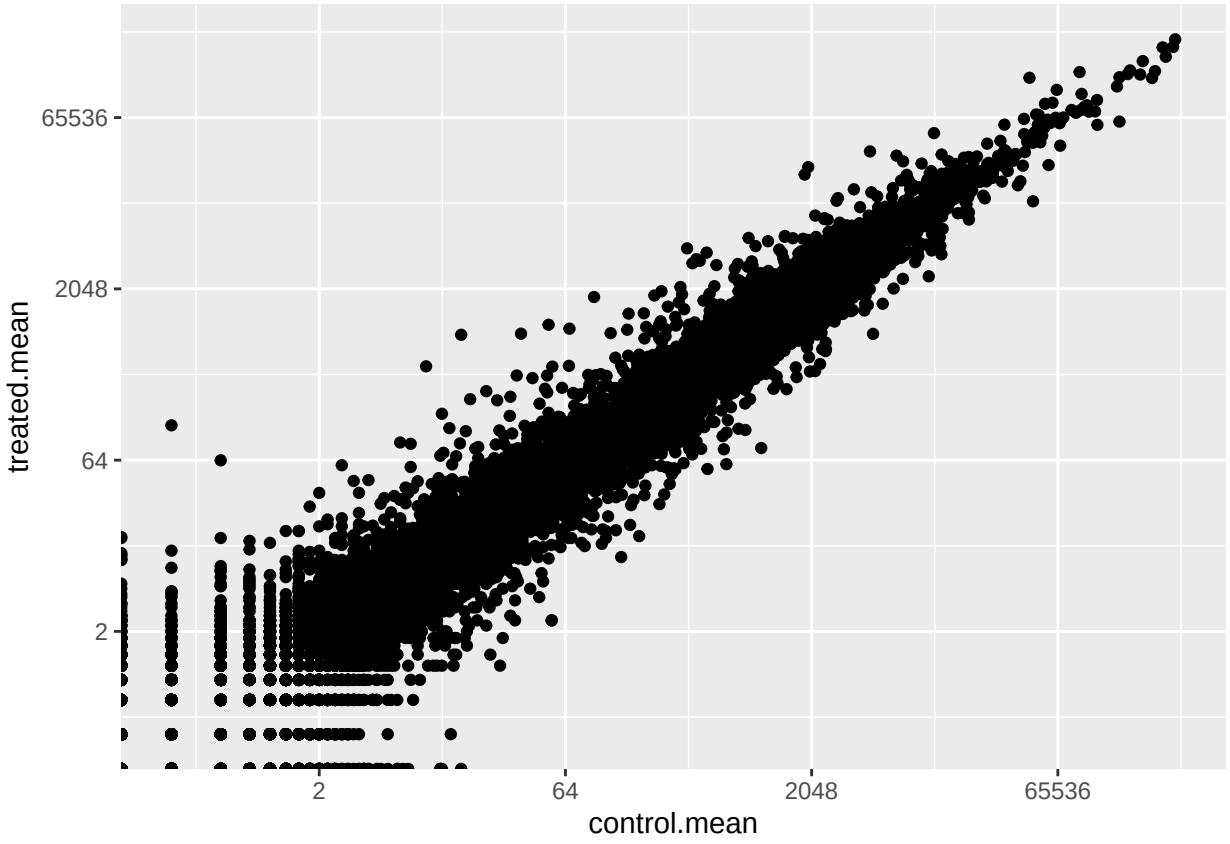


Q6. Try plotting both axes on a log scale. What is the argument to plot() that allows you to do this?

```
ggplot(meancounts, aes(control.mean, treated.mean)) +
  geom_point() +
  scale_x_continuous(trans="log2")+
  scale_y_continuous(trans="log2")
```

```
## Warning: Transformation introduced infinite values in continuous x-axis
```

```
## Warning: Transformation introduced infinite values in continuous y-axis
```



```
# calculate log2foldchange, add it to our meancounts data.frame and inspect the results either with the

meancounts$log2fc <- log2(meancounts[,"treated.mean"]/meancounts[,"control.mean"])
head(meancounts)
```

```
##                 control.mean treated.mean      log2fc
## ENSG00000000003       900.75       658.00 -0.45303916
## ENSG00000000005         0.00         0.00         NaN
## ENSG00000000419       520.50       546.00  0.06900279
## ENSG00000000457       339.75       316.50 -0.10226805
## ENSG00000000460        97.25        78.75 -0.30441833
## ENSG00000000938         0.75         0.00        -Inf
```

A common rule thumb in the field in the field is t focus intially on big changes with a cuffoff log2 fc of +2 or -2.

```
# The NaN is returned when you divide by zero and try to take the log. The -Inf is returned when you tr

#
zero.vals <- which(meancounts[,1:2]==0, arr.ind=TRUE)
```

```
to.rm <- unique(zero.vals[,1])
mycounts <- meancounts[-to.rm,]
head(mycounts)
```

```
##                 control.mean treated.mean      log2fc
## ENSG00000000003       900.75       658.00 -0.45303916
## ENSG00000000419       520.50       546.00  0.06900279
## ENSG00000000457       339.75       316.50 -0.10226805

## ENSG00000000971      5219.00      6687.50  0.35769358
## ENSG00000001036      2327.00      1785.75 -0.38194109
```

> Q7. What is the purpose of the arr.ind argument in the which() function call above? Why would we then take the first column of the output and need to call the unique() function?

arr.ind argument: return row and column indices of the TRUE values unique() function: do not count any row twice if there is a 0 value in both samples.

> Q8. Using the up.ind vector above can you determine how many up regulated genes we have at the greater than 2 fc level?

```
sum(mycounts$log2fc > 2)
```

```
## [1] 250
```

> Q9. Using the down.ind vector above can you determine how many down regulated genes we have at the greater than 2 fc level?

```
sum(mycounts$log2fc < (-2))
```

```
## [1] 367
```

> Q10. Do you trust these results? Why or why not?

Lack of statistical analysis for differences in expression of each gene.

DESeq2 analysis
